dynamic processes in cells
(a systems approach to biology)

jeremy gunawardena
department of systems biology
harvard medical school

lecture 2
8 september 2015
1. homeostasis & microscopic cybernetics
The fixity of the milieu supposes a perfection of the organism such that the external variations are at each instant compensated for and equilibrated ... All of the vital mechanisms, however varied they may be, have always one goal, to maintain the uniformity of the conditions of life in the internal environment .... The stability of the internal environment is the condition for the free and independent life.”

Claude Bernard, Introduction to the Study of Experimental Medicine, 1865
homeostasis and negative feedback

“Before those extremes are reached agencies are automatically called into service which act to bring back towards the mean position the disturbed state”*

“Such disturbances are normally kept within narrow limits, because automatic adjustments within the system are brought into action and thereby wide oscillations are prevented and the internal conditions are held fairly constant.”*

1. “back towards the mean position” – perfect adaptation
2. “wide oscillations are prevented” – dynamical stability

“mg%” is an old unit meaning “mg per 100 mL”; “mg/dL” is now the preferred notation. Normal glucose level is about 100 mg/dL or about $5\text{mM}$.

Table 1.2: Top, glucose levels of six healthy human male subjects during cycling exercise. The subjects followed a weight-maintaining diet for one week and were then studied after an overnight fast of 12-14 hours. Data are given as means plus or minus standard errors, obtained after a 30 minute period of rest and then after continuous upright cycling for 40 minutes. Glucose was measured enzymatically from arterial blood and pulmonary oxygen intake was estimated from expired air. Bottom, glucose levels of six trained cyclists during cycling exercise. The subjects were instructed to keep their diet as constant as possible in the days before the experiment, which was done after an overnight fast. A resting sample was taken and measurements were begun after a five minute cycling warm up. Blood samples were drawn at several time points during continuous cycling and glucose levels were measured with an automated spectrophotometric analyser. The numerical data were not available from the authors and the time points and average glucose levels were determined by blowing up Figure 1 in GSview 4.9, estimating the coordinates of the plotted points and the unit marks on the axes and calculating the underlying x and y values in minutes and mM, respectively. The error bars could not be feasibly extracted.
**perfect adaptation**

**perfect adaptation** - a form of homeostasis in which some property, such as glucose concentration, achieves a steady value ("set point") under suitable conditions, such as after an overnight fast, and that same value is eventually recovered despite a sustained change in some parameter, such as exercise rate.
teleology vs reductionism

Walter Cannon did not explain how homeostasis was achieved by negative feedback. He thought it was due to “The Wisdom of the Body” or “the healing power of nature”. This is teleological thinking:

**teleology** - the function or purpose of an object is a “final cause”, or explanation, of its behaviour.

**aristotle** (384-322 BCE), the world's first great biologist, pointed out that biological organisms exhibit purpose and therefore seem to require teleological explanations.

</tbody>
</table>

we have been struggling with final causes ever since – “Teleology is a lady without whom no biologist can live. Yet he is ashamed to show himself with her in public.” (*)

Engineers had already worked out homeostasis.

Centrifugal governor at a restored windmill in Moulton, Lincolnshire, UK. Design like this dates to the 18th century.

cybernetics - the machine analogy

control problems in physiology are analogous to control problems in engineered systems and may have similar implementations

brains and minds undertake computation and information processing

how to control a simple system (at steady state)

\[ \frac{dx}{dt} = -bx \]

linear, first order system

\[ b > 0 \]

different choices of initial condition \( x(0) \)

\[ b = 2 \]
Proportional control

Try to maintain the system at a set point “r”

Use negative feedback that is proportional to the discrepancy (r - x)

\[ x_c = k_p (r - x) \]

\[ \frac{dx}{dt} = -bx + x_c \]
proportional control

\[ \frac{dx}{dt} + (b + k_p)x = k_pr \]

at steady state, \( \frac{dx}{dt} = 0 \)

\[ x = \left( \frac{1}{1 + b/k_p} \right) r \]

proportional control incurs a **steady-state error** that can be reduced by increasing the controller gain.
biased proportional control

\[ x_c = k_p (r - x) + u \]

\[ \frac{dx}{dt} = -bx + x_c \]

feedback
biased proportional control

\[
\frac{dx}{dt} + (b + k_p)x = k_p r + u
\]

at steady state,

\[
x = \left(\frac{k_p}{b + k_p}\right) r + \left(\frac{u}{b + k_p}\right)
\]

biased proportional control eliminates steady-state error if the bias is fine tuned so that \( u = br \)

the controller requires knowledge of the parameters of the controlled system, which may alter over time or vary between systems

this is not a robust solution
integral control

The control signal is the time integral of the error.
integral control achieves perfect adaptation

\[ \frac{d^2 x}{dt^2} + b \frac{dx}{dt} + k_i x = k_i r \]

at steady state, \( x = r \)

integral control eliminates steady-state error robustly with respect to the parameters

at the expense of increasing the order of the system (and potentially introducing instability)

integral control can be combined with proportional control and derivative control (PID control), to enhance stability and the transient response – multiple control mechanisms are needed to shape the overall behaviour of a controller

evolution has already discovered integral control

but what about dynamical stability?

engineers know that negative feedback can lead to oscillation and instability –

James Clerk Maxwell spent sleepless nights worrying about how the Watt governor could remain stable.

It will be seen that the motion of a machine with its governor consists in general of a uniform motion, combined with a disturbance which may be expressed as the sum of several component motions. These components may be of four different kinds:

1. The disturbance may continually increase.
2. It may continually diminish.
3. It may be an oscillation of continually increasing amplitude.
4. It may be an oscillation of continually decreasing amplitude.

**linear equations are “easy” & fundamental**

\[
\text{order} = n \quad \frac{d^n x}{dt^n} + a_{n-1} \frac{d^{n-1} x}{dt^{n-1}} + \cdots + a_1 \frac{dx}{dt} + a_0 x = 0
\]

**linear problems can be solved analytically**

**linear equations** have the property that any linear combination of solutions is also a solution (“principle of superposition”).

If \( x_1(t) \) and \( x_2(t) \) are solutions, then so is \( \lambda_1 x_1(t) + \lambda_2 x_2(t) \)

**nonlinear equations** do not satisfy superposition and there is no systematic procedure for solving them.

However, nonlinear ODEs can be approximated by linear ODEs in the vicinity of a steady state (next lecture). Hence, knowledge of linear equations is fundamental for understanding nonlinear equations.

Furthermore, biochemical systems conceal a surprising degree of linearity, as we will see when we study the linear framework (lecture 6).
solving linear ODEs of order 1

the first-order, linear ODE

\[ \frac{dx}{dt} = ax \]

has the unique solution

\[ x(t) = e^{at} x(0) \]

where the exponential function \( e^t \) is defined by

\[ e^t = 1 + t + \frac{t^2}{2} + \frac{t^3}{3.2} + \cdots + \frac{t^n}{n!} + \cdots \]

(this definition works generally for complex numbers or matrices *)

* see the lecture notes “Matrix algebra for beginners, Part III”
solving linear ODEs of order 2

the second-order, linear ODE \( \frac{d^2 x}{dt^2} = -a x \quad a > 0 \)

has solutions \( \cos(\sqrt{a}t) \) and \( \sin(\sqrt{a}t) \)

but trigonometric functions are really exponential functions in disguise, over the complex numbers

\[
e^{it} = \cos(t) + i \sin(t) \quad \text{Euler's formula}
\]

\[
\cos(t) = \frac{e^{it} + e^{-it}}{2} \quad \sin(t) = \frac{e^{it} - e^{-it}}{2i}
\]

we only need the exponential function (over the complex numbers) to solve ODEs of order 1 and 2
